

Counter

2.0

Features

- Fixed-function (FF) and universal digital block (UDB) implementations
- 8-, 16-, 24-, or 32-bit counter
- Up, down, or up-and-down configurations
- Optional compare output
- Optional capture input
- Enable and reset inputs for synchronizing with other components
- Continuous or one shot run modes

General Description

The Counter component provides a method to count events. It can implement a basic counter function and offers advanced features such as capture, compare output, and count direction control.

This component can be implemented using FF blocks or UDBs. A UDB implementation typically has more features than an FF implementation. If your design is simple enough, consider using FF and conserve UDB resources for other purposes.

The following table shows the major differences between FF and UDB. For more details about FF resources in the devices, refer to the applicable device datasheet or Technical Reference Manual.

Feature	FF	UDB
No. of bits	8 or 16	8, 16, 24, or 32
Run mode	Continuous or one shot	Continuous or one shot
Counter mode	Down only	Up, down, or up-and-down
Enable input	No (software enable only)	Yes (hardware or software enable)
Capture input	No	Yes
Capture mode	None	Rising edge, falling edge, either edge, or software controlled

Feature	FF	UDB
Capture FIFO	No (one capture register)	Yes (up to four captures)
Reset input	Yes	Yes
Terminal count output	Yes	Yes
Compare output	No	Yes
Compare mode	None	<, ≤, =, ≥, >, or software controlled
Interrupt output	Yes	Yes
Interrupt conditions	TC	TC, capture, and compare
Period register	Yes	Yes
Period reload	Y (always reload on reset or TC)	Y (reload on one or more of reset, TC, capture, compare)
Clock input	Limited to digital clocks in the clock system	Any signal
Sampling clock input	No	Requires an explicit clock signal (component clock) for sampling input signals of the component

When to Use a Counter

The default use of the Counter is to count the number of edge events on the count input. However, there are several other potential uses of the Counter:

- Clock divider: By driving a clock into the count input and using the compare or terminal count output as the divided clock output
- Frequency counter: By connecting a signal with a known period to the enable input of the counter while counting the signal to measure on the count input.
- Tool to measure complementary events such as the output of a quadrature decoder

Note A Timer component is better used in situations focused on measuring the time between events. A PWM component is better used in situations requiring multiple compare outputs with more control features such as center alignment, output kill, and deadband outputs.

Input/Output Connections

This section describes the various input and output connections for the Counter component. Some I/Os may be hidden on the symbol under the conditions listed in the description of that I/O.

Note All signals are active high unless otherwise specified. All inputs to the counter must be synchronized outside of the counter.

Input	May Be Hidden	Description
clock	N	<p>The functional behavior of the clock input differs for the fixed-function Counter compared to the UDB Counter.</p> <ul style="list-style-type: none"> For a fixed-function Counter, there is no count input. A fixed-function Counter updates (decrements its internal counter) on every rising edge of the clock input For a UDB Counter, both the clock and count input appear on the Counter symbol. The clock is used to sample the inputs of the Counter component. The UDB Counter is implemented as a synchronous counter that uses the clock input only as a synchronization clock. All inputs of the Counter must be synchronized to the clock input to avoid setup violations. This also makes sure that the edge-detect circuitry in the UDB Counter implementation functions properly.
Count	Y	<p>In a fixed-function Counter, there is no count input on the Counter symbol. A FF Counter updates its internal count on every rising edge of the clock input.</p> <p>For a UDB Counter, the Counter updates its internal counter with an edge detect logic to determine an update event. The source signal for the update event depends on the clock mode of the UDB Counter. The edge detect logic is clocked using the clock input. Both edges of the count input must meet setup to the clock input; therefore, the maximum count input is one-half of the clock input frequency.</p> <ul style="list-style-type: none"> For a UDB Counter in the Up or Down clock mode, the edge detect logic detects the rising edge of the count input synchronous to the clock input. Depending on whether the Counter is configured as an up counter or down counter, the edge detect event on the count input increments or decrements the Counter, respectively. See Figure 5 on page 25 for a functional description of the Up/Down Counter. For a UDB Counter in the Count Input and Direction clock mode, the edge detect logic detects the rising edge of the count input synchronous to the clock input. Depending on the whether the "updown" signal is a 1 or a 0, the edge detect event on the count input increments or decrements the Counter, respectively. See Figure 7 on page 26 for a functional description of the Counter in Count Input and Direction clock mode. For a UDB Counter in the Clock with UpCnt & DwnCnt clock mode, there is no count input. The Counter update event is determined by a combination of the edge detect logic on UpCnt and DwnCnt signals synchronous to the clock input. See Figure 9 on page 28 for a functional description of the Counter in Clock with UpCnt & DwnCnt clock mode.
upCnt	Y	<p>Increment signal to the counter. When Clock Mode is set to Clock With UpCnt & DwnCnt, this input is used in conjunction with the dwnCnt input and the clock input to allow the Counter to be used as an encoder. A rising edge on this input increments the count value. Both edges of the upCnt input must meet setup to the clock input; therefore, the maximum count input is one-half of the clock input frequency.</p>

Input	May Be Hidden	Description
dwnCnt	Y	Decrement signal to the counter. When Clock Mode of the counter is set to Clock With UpCnt & DwnCnt , this input is used in conjunction with the upCnt input and the clock input to allow the counter to be used as an encoder. A rising edge on this input decrements the count value. Both edges of the dwnCnt input must meet setup to the clock input; therefore, the maximum count input is one-half of the clock input frequency.
up_ndown	Y	Defines the counting direction of the counter. This input is only available if Clock Mode is set to enable direction control (Count Input and Direction). On a rising edge of the count input, a '1' on this input causes the counter to increment, and a '0' on this input causes the counter to decrement.
reset	N	<p>The reset input resets the counter to the starting value.</p> <ul style="list-style-type: none"> For the Up Counter configuration, the starting value is zero. For Down Counter, Count Input and Direction, and Clock With UpCnt & DwnCnt configurations, the starting value is set to the current period register value <p>The reset input is sampled on the count/clock input.</p> <p>Note For PSoC 3 ES2 silicon, the Terminal Count pin for the fixed-function counter is held high during reset. A schematic fix for this is provided under Reset in Fixed-Function Block in the Functional Description section of this datasheet.</p> <p>For PSoC 3 Production or later silicon, the Terminal Count pin for the fixed-function counter is held low during reset. The reset input is used to reset the control register in PSoC 3 Production and PSoC 5 UDB counter implementation, and also to implement the One-Shot Run Mode feature</p>
enable	Y	Hardware enable of the counter. This input is visible when the Enable Mode parameter is set to Hardware .
capture	Y	<p>Captures the current count value to a capture register or FIFO. This input is visible if the Capture Mode parameter is set to any mode other than None. Capture may take place on a rising edge, falling edge, or either edge applied to this input, depending on the Capture Mode setting.</p> <p>The capture input is sampled on the clock input.</p>

Output	May Be Hidden	Description
tc	N	Terminal count is a synchronous output that indicates that the count value is equal to the terminal count. The output is synchronous to the clock input of the Counter. The signal goes high one clock cycle after the count value matches the terminal count and stays high while the count value is equal to the terminal count. If the Counter is disabled when the count is at terminal count, the output stays high until the Counter is re-enabled.
comp	Y	The compare output indicates the counter value compared to the compare value based on the configuration in the Compare Mode parameter. The output goes high one clock cycle of the clock input, after the compare event has taken place.
interrupt	N	The interrupt output is driven by the interrupt sources configured in the hardware. All sources are ORed together to create the final output signal. The sources of the interrupt can be: Compare, Terminal Count or Capture.

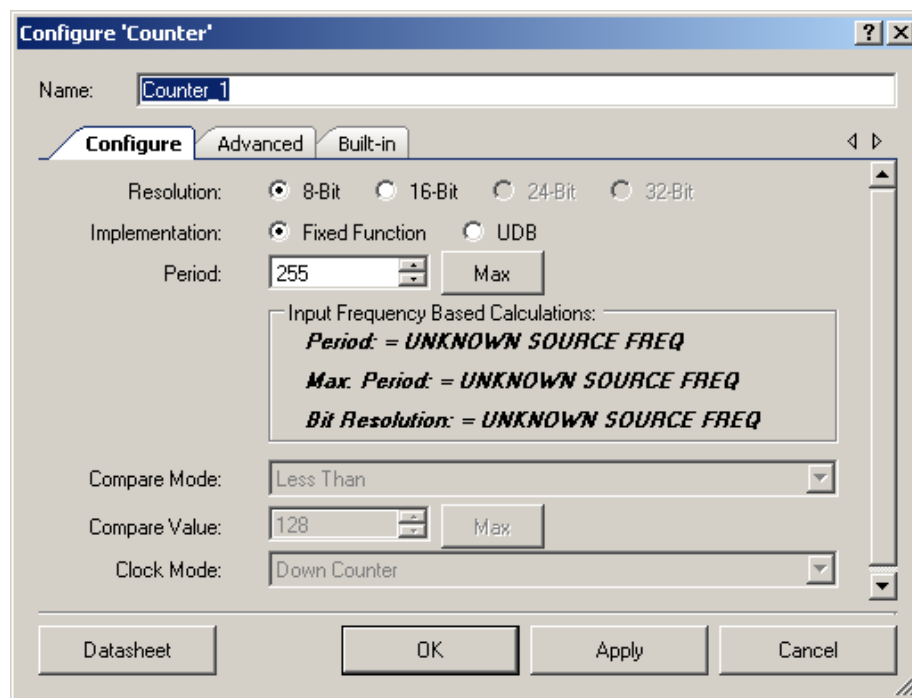

Component Parameters

Drag a Counter onto your design and double-click it to open the **Configure** dialog.

Hardware versus Software Configuration Options

Hardware configuration options change the way the project is synthesized and placed in the hardware. You must rebuild the hardware if you make changes to any of these options. Software configuration options do not affect synthesis or placement. When setting these parameters before build time you are setting their initial value, which may be modified at any time with the API provided. Most parameters described in the following sections are hardware options. The software options are noted as such.

Configure Tab

Resolution

The **Resolution** parameter defines the bit-width resolution of the Counter component. This value may be set to 8, 16, 24 or 32 for maximum count values of 255, 65535, 16777215, and 4294967295 respectively.

Implementation

The **Implementation** parameter allows you to choose between a fixed-function block implementation and a UDB implementation of the Counter. If you select **Fixed Function**, then UDB functions become disabled.

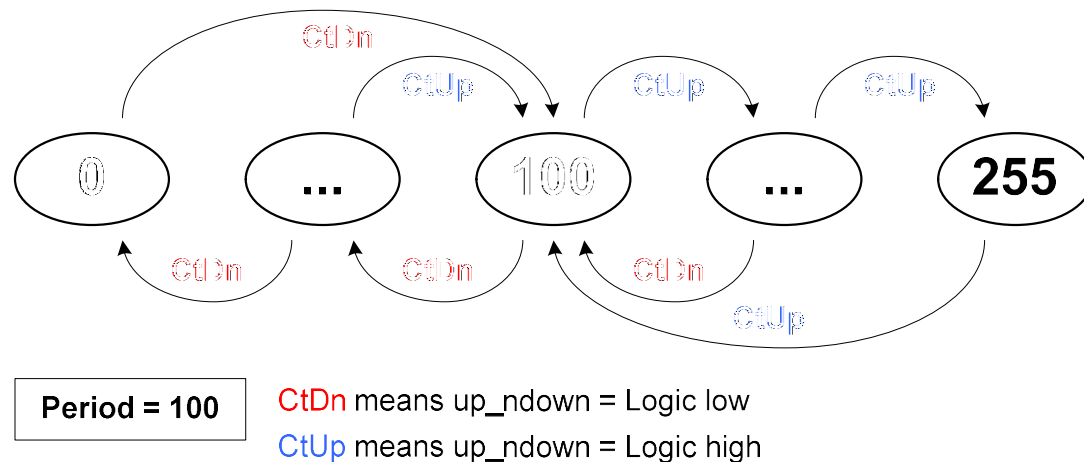

Period (Software Option)

The **Period** parameter defines the max counts value (or rollover point) for the Counter component. This parameter defines the initial value loaded into the period register, which can be changed at any time by the software with the Counter_WritePeriod() API.

The limits of this value are defined by the **Resolution** parameter. For 8-, 16-, 24-, and 32-bit **Resolution** parameters, the maximum value of the **Period** value is defined as $(2^8) - 1$, $(2^{16}) - 1$, $(2^{24}) - 1$, and $(2^{32}) - 1$ or 255, 65535, 16777215, and 4294967295 respectively.

When **Clock Mode** is configured as **Clock with UpCnt & DwnCnt** or **Count Input and Direction**, the counter is set to the period at start and any time the counter overflows or underflows. In these clock modes, do not set the period value to all 1s or all 0s. Instead, the normal practice is to keep the period value at the midpoint of the period range (for an 8-bit counter, 0x7F). **Figure 1** shows **Clock Mode** set to **Count Input and Direction**.

Figure 1. Clock Mode

Compare Mode (Software Option)

The **Compare Mode** parameter configures the operation of the comp output signal. This signal is the status of a compare between the compare value parameter and current counter value. This parameter defines the initial setting. You can change it at any time to reconfigure the compare operation of the Counter component.

Compare Mode can be set to any of the following values:

- **Less Than** – The counter value is less than the compare value
- **Less Than Or Equal** – The counter value is less than or equal to the compare value
- **Equal To** – The counter value is equal to the compare value
- **Greater Than** – The counter value is greater than the compare value

- **Greater Than Or Equal** – The counter value is greater than or equal to the compare value
- **Software Controlled** – The compare mode can be set during run time with the Counter_SetCompareMode() API call to any one of the other five compare modes on this list.

Compare Value (Software Option)

The **Compare Value** parameter defines the initial value loaded into the compare register of the counter. This value is used in conjunction with the **Compare Mode** parameter to define the operation of the compare output.

This value can be any unsigned integer from 0 to $(2^{\text{Resolution}} - 1)$, but it must be less than or equal to the period value.

Clock Mode

The **Clock Mode** parameter configures how the Counter will count. This mode can be set to any of the following values:

- **Count Input and Direction** – Counter is a bidirectional counter. It counts up while the up_ndown input is high on each rising edge of the input clock and counts down while up_ndown is low on each rising edge of the input clock.
- **Clock With UpCnt & DwnCnt** – Counter is a bidirectional counter. It increments the counter for each rising edge on the upCnt input and decrements the counter for each rising edge of the dwnCnt input, with respect to the clock input. In this mode, the clock input freq must be at least 2x the freq of UpCnt and DwnCnt inputs.
- **Up Counter** – Counter is an up counter only. It increments on a rising edge of the count input with respect to the clock signal while the counter is enabled.
- **Down Counter** – Counter is a down counter only. It decrements on a rising edge of the count input with respect to the clock signal while the counter is enabled.

Reload Counter:

☒ On Reset ☒ On TC

Interrupt: ☐ On TC ☐ On Capture ☐ On Compare

Capture Mode

The **Capture Mode** parameter configures when a capture takes place. The capture input is sampled on the rising edge of the clock input. This mode can be set to any of the following values:

- **None** – No capture implemented. The capture input pin is hidden.
- **Rising Edge** – Capture the counter value on a rising edge of the capture input with respect to the clock input.
- **Falling Edge** – Capture the counter value on a falling edge of the capture input with respect to the clock input.
- **Either Edge** – Capture the counter value on either edge of the capture input with respect to the clock input.
- **Software Controlled** – Set the mode at run time by setting the capture mode bits in the control register Counter_CTRL_CAPMODE_MASK with the enumerated capture mode types. These are defined in the *Counter.h* header file.

Enable Mode

The **Enable Mode** parameter configures the enable implementation of the counter. The enable input is sampled on the rising edge of the clock input. This mode can be set to any of the following values:

- **Software Only** – The Counter is enabled based on the enable bit of the control register only.
- **Hardware Only** – The Counter is enabled based on the enable input only.
- **Hardware and Software** – The Counter is enabled if both hardware and software enables are true.

Run Mode

The **Run Mode** parameter allows you to configure the Counter component to run continuously or in one-shot mode:

- **Continuous** – The Counter runs continuously while it is enabled.
- **One Shot** – The Counter runs through a single period and stops at terminal count. After it is reset, it begins another single cycle. On stop, for a UDB counter, it reloads period into the count register; for a fixed-function counter, the count register remains at terminal count.

Reload Counter

The **Reload Counter** parameters allow you to configure when the counter value is reloaded. The counter value is reloaded when one or more of the following selected events occur. The counter is reloaded with its start value on a reload event.

- **On Capture** – The counter value is reloaded when a capture event has occurred. By default, this parameter is cleared. This parameter is only shown when **UDB** is selected for **Implementation**.
- **On Compare** – The counter value is reloaded when a compare true event has occurred. By default, this parameter is cleared. This parameter is only shown when **UDB** is selected for **Implementation**.
- **On Reset** – The counter value is reloaded when a reset event has occurred. By default this parameter is selected. This parameter is always shown. For a fixed-function counter, it cannot be changed. For a UDB counter, it can be turned off.
- **On TC** – The counter value is reloaded when the counter has overflowed (in up count mode) or underflowed (in down count mode). By default, this parameter is selected. For a fixed-function counter, it cannot be changed. For a UDB counter, it can be turned off.

When the clock mode is set to **Clock With UpCnt & DwnCnt** this option reloads to the period value when counter is 0x00 or all 0xFF.

The following table lists the reload and terminal count conditions for the various Clock Modes of the Counter component.

Clock Mode	Terminal Count Condition	Counter Start Value and Reload Value on a Reload Event
Fixed Function Counter	When counter equals 0.	The start and the reload value of the Counter is the Period value of the component.
UDB Up Counter	When counter equals Period value	The start and the reload value of the Counter is 0.
UDB Down Counter	When counter equals 0.	The start and the reload value of the Counter is the Period value of the component.
UDB Count Input and Direction	When the Counter is all 1s (0xFF for 8-bit, 0xFFFF for 16-bit, 0xFFFFFFFF for 24-bit, or 0xFFFFFFFF for a 32-bit Counter) when it is counting up OR when the Counter equals 0 when it is counting down.	The start and reload value of the Counter is the Period value of the component. If there is no reload condition, the counter wraps around and continues counting without a counter register reload.
UDB Clock with UpCnt and DwnCnt	When the Counter is all 1s (0xFF for 8-bit, 0xFFFF for 16-bit, 0xFFFFFFFF for 24-bit, or 0xFFFFFFFF for a 32-bit Counter) when it is counting up OR when the Counter equals 0 when it is counting down.	The start and reload value of the Counter is the Period value of the component. If there is no reload condition, then the counter wraps around and continues counting without a counter register reload.

Interrupt

The **Interrupt** parameters allow you to configure the initial interrupt sources. An interrupt will be generated when one or more of the following selected events occur. This parameter defines an initial configuration. The software can reconfigure this mode at any time.

- **On TC** – This parameter is always active; by default, it is not selected.
- **On Capture** – By default, this parameter is not selected. It is always shown, but it is only active when the **Implementation** parameter is set to **UDB**.
- **On Compare** – By default, this parameter is not selected. It is always shown, but it is only active when the **Implementation** parameter is set to **UDB**.

Clock Selection

For the Counter component,

- When the **Clock Mode** parameter is set to **Up Counter** or **Down Counter**, the count input can be any signal for which the rising edges are counter. The clock input to the component samples the count input and must be at least twice the frequency of the count input.

- When the **Clock Mode** parameter is set to **Count Input and Direction**, the clock input can be any signal for which the rising edges are counter. The counter will count up or down depending on the up_ndown input.
- When the **Clock Mode** parameter is set to **Clock With UpCnt & DwnCnt**, the upCnt and dwnCnt rising edges are sampled with respect to the clock input. The counter counts on a rising edge on the upCnt signal and down on the rising edge on the dwnCnt signal.

See the Clock component datasheet and the appropriate device datasheet for more details on PSoC 3 or PSoC 5 clocking systems.

Fixed-Function Components

When configured to use the FF block in the device, the Counter component has the following restrictions:

- The count input must be a digital clock from the clock system.
- If the frequency of the clock is to be the same as bus clock, the clock must actually be the bus clock.

Open the **Configure** dialog of the appropriate Clock component to configure the **Clock Type** parameter as **Existing** and the **Source** parameter as **BUS_CLK**. A clock at this frequency cannot be divided from any other source, such as the master clock, IMO, and so on.

UDB-based Components

You can connect any digital signal from any source to the count/clock input. The frequency of that signal is limited to the frequency range defined in the [DC and AC Electrical Characteristics \(UDB Implementation\)](#) section in this datasheet. The count input must, at most, be half the frequency as that of the clock input in any of the Counter Clock modes.

Placement

PSoC Creator places the Counter component in the device based on the **Implementation** parameter. If it is set to **Fixed Function**, this component is placed in any available FF counter/timer block. If it is set to **UDB**, this component is placed around the UDB array in the best possible configuration.

Resources

Resolution	Digital Blocks					API Memory (Bytes)		Pins (per External I/O)
	Datapaths	Macro cells	Status Registers	Control Registers	Counter7	Flash	RAM	
8 Bits UDB Basic Up or Down Counter ¹	1	6	1	1	0	267	5	0
8 Bits UDB Counter with direction ²	1	10	1	1	0	267	5	0
8 Bits FF Counter ³	0	0	0	0	0	239	5	0
16 Bits UDB Basic Up or Down Counter ¹	2	6	1	1	0	318	6	0
16 Bits UDB Counter with direction ²	2	10	1	1	0	319	6	0
16 Bits FF Counter ³	0	0	0	0	0	255	6	0
24 Bits Basic Counter ¹	3	6	1	1	0	308	8	0
32 Bits Basic Up or Down Counter ¹	4	6	1	1	0	308	8	0

¹ The UDB Counter with corresponding resolution is configured as a simple Up Counter or Down Counter with Software Only Enable mode, Continuous Run mode, Reload on Reset and Interrupt on TC with no Capture mode.

² The FF Counter with corresponding resolution is configured for Continuous Run mode and Interrupt on TC with no Capture mode for the corresponding resolution

³ The UDB Counter with corresponding resolution is configured in the “Count Input and Direction” Clock mode with Software Only Enable mode, Continuous Run mode, Reload on Reset and Interrupt on TC with no Capture mode.

Application Programming Interface

Application Programming Interface (API) routines allow you to configure the component using software. The following table lists and describes the interface to each function. The subsequent sections cover each function in more detail.

By default, PSoC Creator assigns the instance name “Counter_1” to the first instance of a component in a given design. You can then rename the instance to any unique value that follows the syntactic rules for identifiers. The instance name becomes the prefix of every global function name, variable, and constant symbol. For readability, the instance name used in the following table is “Counter.”

Function	Description
Counter_Start()	Sets the initVar variable, calls the Counter_Init() function, and then calls the Enable function.
Counter_Stop()	Disables the Counter.
Counter_SetInterruptMode()	Enables or disables the sources of the interrupt output.
Counter_ReadStatusRegister()	Returns the current state of the status register.
Counter_ReadControlRegister()	Returns the current state of the control register.
Counter_WriteControlRegister()	Sets the bit-field of the control register.
Counter_WriteCounter()	Writes a new value directly into the counter register.
Counter_ReadCounter()	Forces a capture, and then returns the capture value.
Counter_ReadCapture()	Returns the contents of the capture register or the output of the FIFO.
Counter_WritePeriod()	Writes the period register.
Counter_ReadPeriod()	Reads the period register.
Counter_WriteCompare()	Writes the compare register.
Counter_ReadCompare()	Reads the compare register.
Counter_SetCompareMode()	Sets the compare mode.
Counter_SetCaptureMode()	Sets the capture mode.
Counter_ClearFIFO()	Clears the capture FIFO.
Counter_Sleep()	Stops the Counter and saves the user configuration.
Counter_Wakeup()	Restores and enables the user configuration.
Counter_Init()	Initializes or restores the Counter per the Configure dialog settings.
Counter_Enable()	Enables the Counter.
Counter_SaveConfig()	Saves the Counter configuration.
Counter_RestoreConfig()	Restores the Counter configuration.

Global Variables

Variable	Description
Counter_initVar	Indicates whether the Counter has been initialized. The variable is initialized to 0 and set to 1 the first time Counter_Start() is called. This allows the component to restart without reinitialization after the first call to the Counter_Start() routine. If reinitialization of the component is required, then the Counter_Init() function can be called before the Counter_Start() or Counter_Enable() function.

void Counter_Start(void)

Description: This is the preferred method to begin component operation. Counter_Start() sets the initVar variable, calls the Counter_Init() function, and then calls the Counter_Enable() function.

Parameters: None

Return Value: None

Side Effects: If the initVar variable is already set, this function only calls the Counter_Enable() function.

void Counter_Stop(void)

Description: Disables the Counter only in software enable modes.

Parameters: None

Return Value: None

Side Effects: If **Enable Mode** is set to **Hardware Only**, this function has no effect.

void Counter_SetInterruptMode(uint8 interruptSource)

Description: Enables or disables the sources of the interrupt output.

Parameters: uint8: interrupt sources. For bit definitions, refer to the [Status Register](#) section of this datasheet.

Return Value: None

Side Effects: The bit locations are different between FF and UDB. Mask #defines are provided to encapsulate the differences.

uint8 Counter_ReadStatusRegister(void)

Description: Returns the current state of the status register.

Parameters: None

Return Value: uint8: Current status register value. The status register bits are:

[7]: Unused (0)

[6]: FIFO not empty

[5]: FIFO full

[4]: Capture status

[3]: Underflow status

[2]: Overflow status

[1]: A0 Zero status

[0]: Compare output

For bit definitions, refer to the [Status Register](#) section of this datasheet.

Side Effects: Some of these bits are cleared when status register is read. Clear-on-read bits are defined in the [Status Register](#) section of this datasheet.

uint8 Counter_ReadControlRegister(void)

Description: Returns the current state of the control register. This function is available only if one of the modes defined in the control register is actually used.

Parameters: None

Return Value: uint8: Current control register value. The control register bits are:

[7]: Counter Enable

[6:5]: Unused

[4:3]: Capture Mode select

[2:0]: Compare Mode select

For bit definitions, see the [Control Register](#) section of this datasheet.

Side Effects: None

void Counter_WriteControlRegister(uint8 control)

Description: Sets the bit field of the control register. This function is available only if one of the modes defined in the control register is actually used.

Parameters: uint8: Control register bit field. The control register bits are:
[7]: Counter Enable
[6:5]: Unused
[4:3]: Capture Mode select
[2:0]: Compare Mode select
For bit definitions, see the [Control Register](#) section of this datasheet.

Return Value: None

Side Effects: None

void Counter_WriteCounter(uint8/16/32 count)

Description: Writes a new value directly into the counter register.

Parameters: uint8/16/32: New counter value. For 24-bit Counters, the parameter is uint32.

Return Value: None

Side Effects: Overwrites the counter value. This may cause undesired behavior on the compare output, terminal count output, or period width. This is not an atomic write and the function may be interrupted. The Counter should be disabled before calling this function.

uint8/16/32 Counter_ReadCounter(void)

Description: Forces a capture then returns the capture value.

Parameters: None

Return Value: uint8/16/32: Current counter value. For 24-bit Counters, the return type is uint32.

Side Effects: Returns the contents of the capture register or the output of the FIFO (UDB only).

uint8/16/32 Counter_ReadCapture(void)

Description: Returns the contents of the capture register or the output of the FIFO (UDB only).

Parameters: None

Return Value: uint8/16/32: Current capture value. For 24-bit Counters, the return type is uint32.

Side Effects: None

void Counter_WritePeriod(uint8/16/32 period)

Description: Writes the period register.

Parameters: uint8/16/32: New period value. For 24-bit Counters, the parameter is uint32.

Return Value: None

Side Effects: The period of the counter output does not change until Counter is reloaded.

uint8/16/32 Counter_ReadPeriod(void)

Description: Reads the period register.

Parameters: None

Return Value: uint8/16/32: Current period value. For 24-bit Counters, the return type is uint32.

Side Effects: None

void Counter_WriteCompare(uint8/16/32 compare)

Description: Writes the compare register. This function is available only for UDB implementation.

Parameters: uint8/16/32: New compare value. For 24-bit Counters, the parameter is uint32.

Return Value: None

Side Effects: The compare output may change immediately depending on the value written and the current value of the Counter.

uint8/16/32 Counter_ReadCompare(void)

Description: Reads the compare register. This function is available only for UDB implementation.

Parameters: None

Return Value: uint8/16/32: Current compare value For 24-bit Counters, the return type is uint32.

Side Effects: None

void Counter_SetCompareMode(uint8 compareMode)

Description: Sets the compare mode. This function is available only for UDB implementation and when software compare mode is selected.

Parameters: uint8: Enumerated compare mode. Also see the [Control Register](#) section.

```
Counter__B_COUNTER__LESS_THAN
Counter__B_COUNTER__LESS_THAN_OR_EQUAL
Counter__B_COUNTER__EQUAL
Counter__B_COUNTER__GREATER_THAN
Counter__B_COUNTER__GREATER_THAN_OR_EQUAL
Counter__B_COUNTER__SOFTWARE
```

Return Value: None

Side Effects: The compare output may change immediately depending on the value written and the current value of the counter.

void Counter_SetCaptureMode(uint8 captureMode)

Description: Sets the capture mode. This function is available only for UDB implementation and when the **Capture Mode** parameter is set to **Software Controlled**.

Parameters: uint8: Enumerated capture mode. Also see the [Control Register](#) section.

```
Counter__B_COUNTER__NONE
Counter__B_COUNTER__RISING_EDGE
Counter__B_COUNTER__FALLING_EDGE
Counter__B_COUNTER__EITHER_EDGE
Counter__B_COUNTER__SOFTWARE_CONTROL
```

Return Value: None

Side Effects: None

void Counter_ClearFIFO(void)

Description: Clears the capture FIFO. This function is available only for UDB implementation. Refer to [UDB FIFOs](#) in the [Functional Description](#) section of this datasheet.

Parameters: None

Return Value: None

Side Effects: None

void Counter_Sleep(void)

Description: This is the preferred routine to prepare the component for sleep. The Counter_Sleep() routine saves the current component state. Then it calls the Counter_Stop() function and calls Counter_SaveConfig() to save the hardware configuration.

Call the Counter_Sleep() function before calling the CyPmSleep() or the CyPmHibernate() function. Refer to the PSoC Creator *System Reference Guide* for more information about power-management functions.

Parameters: None

Return Value: None

Side Effects: For FF implementation, all registers are retained across low-power modes. For UDB implementation, the control register and counter value register are saved and restored. Additionally, when calling Counter_Sleep, the enable state is stored in case you call Counter_Sleep() without calling Counter_Stop().

void Counter_Wakeup(void)

Description: This is the preferred routine to restore the component to the state when Counter_Sleep() was called. The Counter_Wakeup() function calls the Counter_RestoreConfig() function to restore the configuration. If the component was enabled before the Counter_Sleep() function was called, the Counter_Wakeup() function will also re-enable the component.

Parameters: None

Return Value: None

Side Effects: Calling the Counter_Wakeup() function without first calling the Counter_Sleep() or Counter_SaveConfig() function may produce unexpected behavior.

void Counter_Init(void)

Description: Initializes or restores the component according to the customizer Configure dialog settings. It is not necessary to call Counter_Init() because the Counter_Start() routine calls this function and is the preferred method to begin component operation.

Parameters: None

Return Value: None

Side Effects: All registers will be set to values according to the customizer **Configure** dialog.

void Counter_Enable(void)

Description: Activates the hardware and begins component operation. It is not necessary to call Counter_Enable() because the Counter_Start() routine calls this function, which is the preferred method to begin component operation. This function enables the Counter for either of the software controlled enable modes.

Parameters: None

Return Value: None

Side Effects: If the **Enable Mode** parameter is set to **Hardware Only**, this function has no effect on the operation of the Counter.

void Counter_SaveConfig(void)

Description: This function saves the component configuration and nonretention registers. It will also save the current component parameter values, as defined in the **Configure** dialog or as modified by appropriate APIs. This function is called by the Counter_Sleep() function.

Parameters: None

Return Value: None

Side Effects: None

void Counter_RestoreConfig(void)

Description: This function restores the component configuration and nonretention registers. It will also restore the component parameter values to what they were prior to calling the Counter_Sleep() function.

Parameters: None

Return Value: None

Side Effects: Calling this function without first calling the Counter_Sleep() or Counter_SaveConfig() function may produce unexpected behavior.

Conditional Compilation Information

The Counter component API files require two conditional compile definitions to handle the multiple configurations it must support. It is required that the API files conditionally compile on the **Resolution** and **Implementation** parameters chosen between the FF or UDB block. The two conditions defined are based on these parameters. The API files should never use these parameters directly but should use the two defines listed here.

Counter_DataWidth

The DataWidth define is assigned to the **Resolution** value at build time. It is used throughout the API to compile in the correct data width types for the API functions relying on this information.

Counter_UsingFixedFunction

The UsingFixedFunction define is used mostly in the header file to make the correct register assignments. This is necessary because the registers provided in the FF block are different than those used when the component is implemented in UDBs. In some cases, this define is also used with the DataWidth define because the FF block is limited to 16 bits maximum data width.

Sample Firmware Source Code

PSoC Creator provides numerous example projects that include schematics and example code in the Find Example Project dialog. For component-specific examples, open the dialog from the Component Catalog or an instance of the component in a schematic. For general examples, open the dialog from the Start Page or **File** menu. As needed, use the **Filter Options** in the dialog to narrow the list of projects available to select.

Refer to the “Find Example Project” topic in the PSoC Creator Help for more information.

Functional Description

General Operation

The Counter component can count in one direction (either up or down) or both directions, depending on the **Clock Mode** parameter setting.

- If set to **Up Counter** or **Down Counter**, the component counts in only one direction. The counter register increments or decrements once per rising edge on the count input with respect to the clock input.
- If set to **Clock Input and Direction** or **Clock With UpCnt & DwnCnt**, the component can count in both directions, based on the upCnt, dwnCnt, and up_ndown inputs. These inputs are described in detail in the [Input/Output Connections](#) section of this datasheet.

Counter Overflow/Underflow

Counter underflow and overflow can occur in any clock mode. Bits are available in the status register to indicate when the overflow or underflow has occurred. Bits in the mode register exist to control whether an int is generated on these conditions.

Clock Mode	Overflow occurs when	Underflow occurs when
Down Counter	Not defined. Interrupt generation should be masked.	Counter register equals 0.
Up Counter	Counter register equals period register	Not defined. Interrupt generation should be masked.

Clock Mode	Overflow occurs when	Underflow occurs when
Clock Input and Direction	Counter register equals 0xFF, 0xFFFF, 0xFFFFFFFF, or 0xFFFFFFFF	Counter register equals 0
Clock With UpCnt & DwnCnt	Counter register equals 0xFF, 0xFFFF, 0xFFFFFFFF, or 0xFFFFFFFF	Counter register equals 0

Counter Outputs

The counter register may be monitored and reloaded. Two outputs, tc and comp, are available for monitoring the current value of the counter register and may be configured as reload events. Refer to the [Input/Output Connections](#) section for more details.

The counter register is reloaded from a period register. The following table shows how terminal count and reload work for each of the **Clock Mode** settings:

Clock Mode	tc Output is Active When	Counter is Reloaded with
Down Counter	One clock input cycle after counter register is equal to 0	Contents of period register as soon as counter register is equal to 0
Up Counter	One clock input cycle after counter register equals the period register	Counter is reset to 0 as soon as counter register equals period register
Clock Input and Direction	One clock input cycle after counter register rolls over to 0	None – counter rolls over
Clock With UpCnt & DwnCnt	One clock input cycle after counter register is equal to 0	None – counter rolls over

The comp output continually indicates the counter value compared to the compare value. The **Compare Mode** parameter is configurable to all of the standard modes (for example, **Less Than Or Equal**, **Greater Than**, and so on). This can be used to create different output waveforms while the counter is counting. The comp output is synchronous to the clock input of the Counter.

Counter Inputs

A capture operation can be done in either hardware or firmware. The current value in the counter register is copied into either a capture register or a FIFO. Firmware can then read the captured value at a later time.

Reset and enable features allow the Counter component to be synchronized to other components. The Counter component counts only when enabled and not held in reset. It may be reset or enabled by either hardware or firmware.

Counter Interrupt

An interrupt output is available for communicating event occurrences to the CPU or to other components. The interrupt can be set to be active on a combination of one or more events. The

interrupt handler should be designed with careful consideration for determining the source of the interrupt and whether it is edge- or level-sensitive, and clearing the source of the interrupt.

Counter Registers

There are two registers: status and control. Refer to the [Registers](#) section.

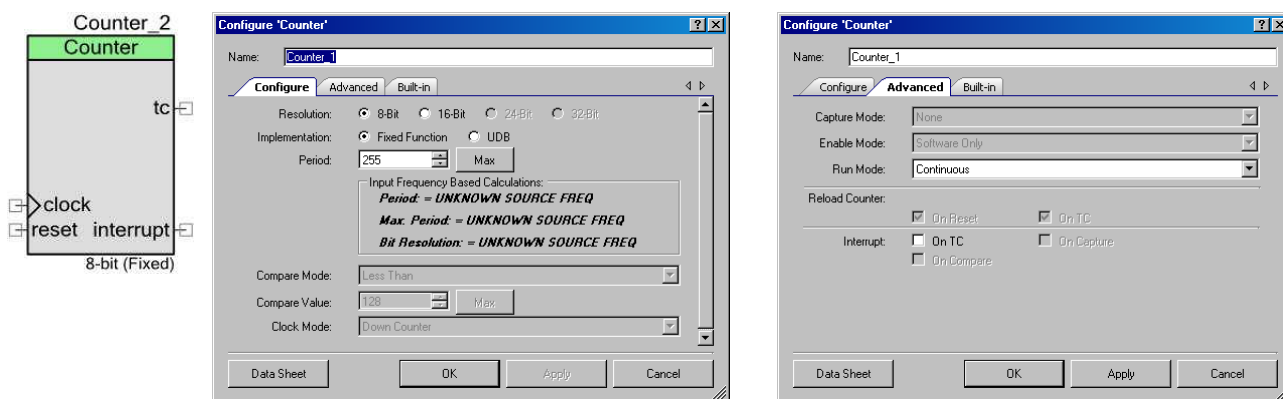

Configurations

The following sections describe a few of the different Clock component configurations.

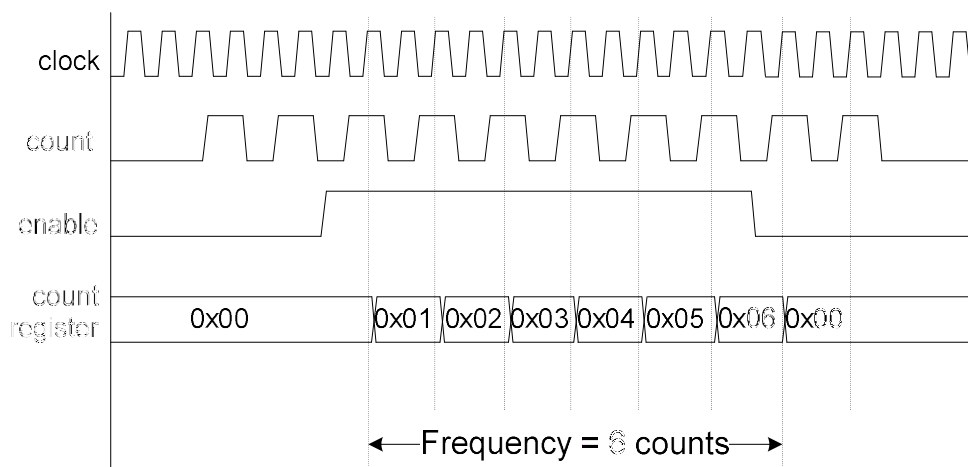

Default Configuration

When you drag a Counter component onto a PSoC Creator schematic, the default configuration is an 8-bit, FF counter that decrements the counter register on a rising edge at the clock input. [Figure 2](#) shows the default component symbol and **Configure** dialog tabs.

Figure 2. Default Configuration

[Figure 3](#) shows the timing diagram for the default configuration.

Figure 3. Default Configuration Waveform

UDB 8-bit Up/Down Counter Configuration

In this configuration, the count register either increments or decrements on the rising edge at the clock input, depending on the clock mode selected. If the clock mode selected is **Up Counter**, the count register increments from 0 to period value. If the clock mode selected is **Down Counter**, then the count register decrements from period value to 0.

Figure 4 shows the UDB 8-bit Up/Down Counter symbol and **Configure** dialog tabs

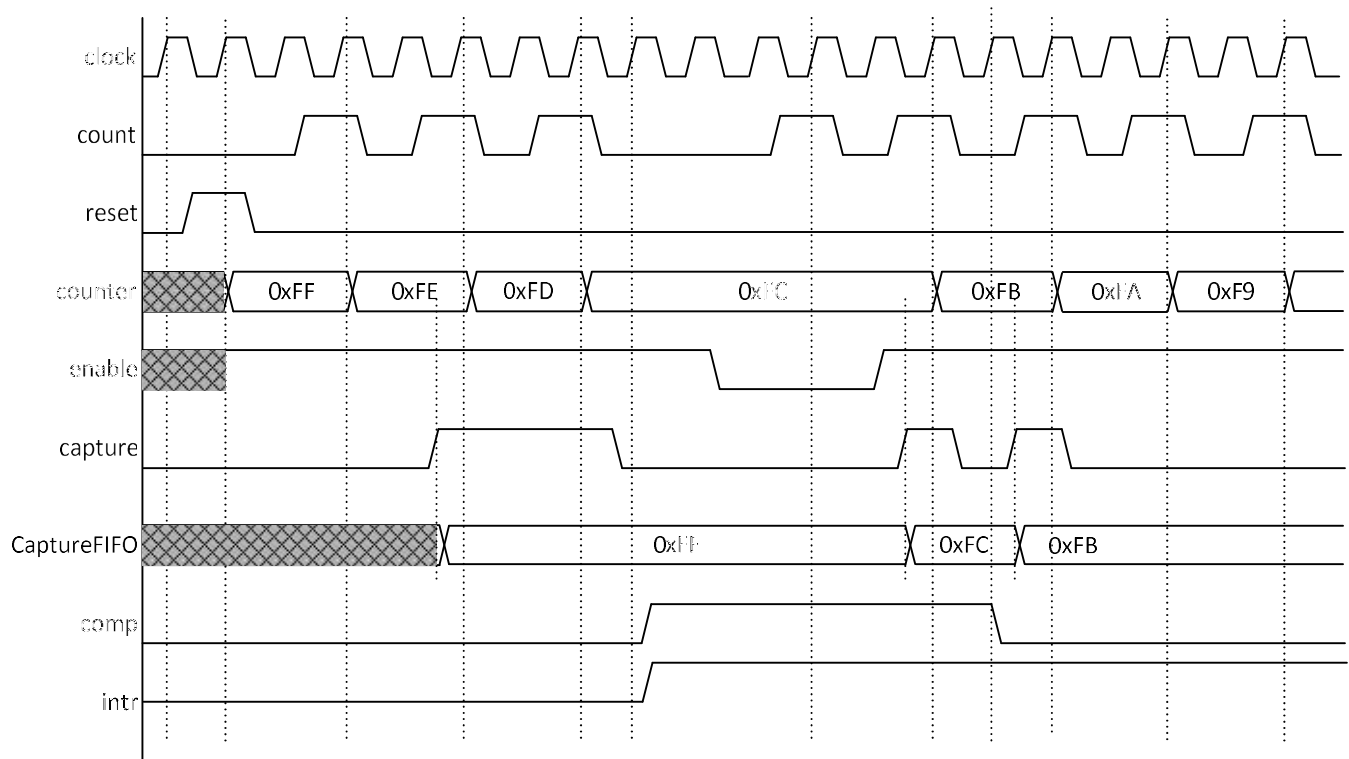

Figure 4. UDB 8-bit Up/Down Counter Configuration

Figure 5 shows the timing diagram for the UDB 8-bit Up/Down Counter configuration.

Figure 5. UDB 8-bit Up/Down Counter Configuration Waveform

Timing Diagram for the Basic Down Counter

Clock Input and Direction Configuration

In this configuration, the count register either increments or decrements, based on the signal to the up_ndown input terminal. When the up_ndown input receives a high signal, the counter increments on the rising edge of the count input. When the up_ndown input receives a low signal, the counter decrements on the rising edge of the count input.

Figure 6 shows the **Clock input and Direction** configuration symbol and **Configure** dialog tabs

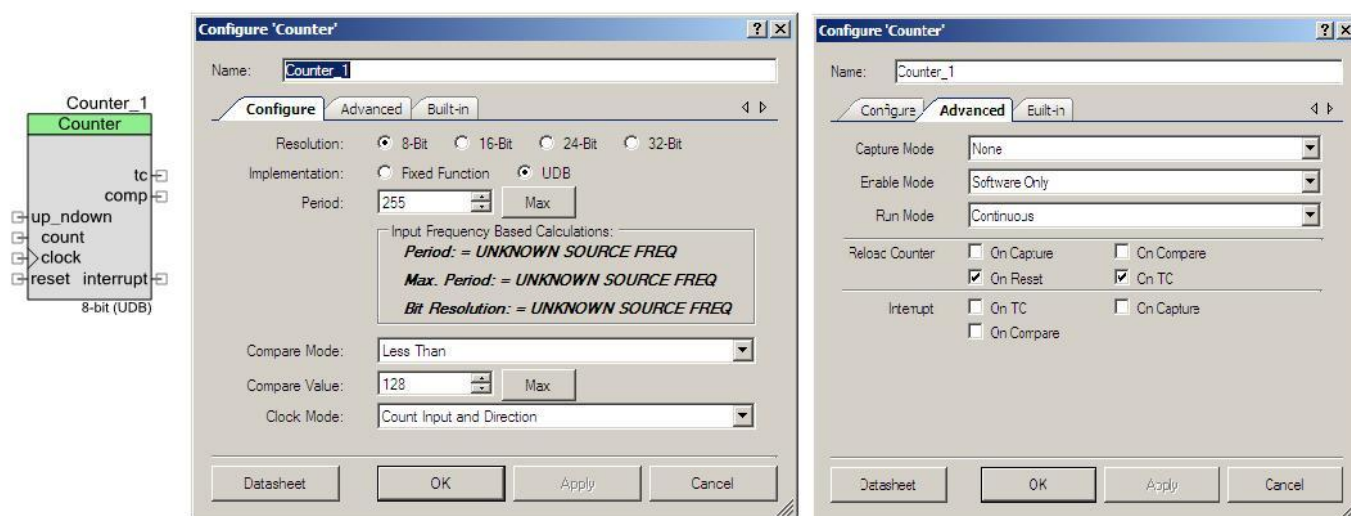

Figure 6. Clock Input and Direction Configuration

Figure 7 shows the timing diagram for the **Clock Input and Direction** mode configuration

Figure 7. Clock Input and Direction Mode Configuration Waveform

Timing Diagram for Clock with Direction

Clock with UpCnt and DwnCnt Configuration

In this configuration, the count input is absent. The Counter either increments or decrements, based on the signal to the upCnt and downCnt inputs.

Figure 8 shows the **Clock with UpCnt & DwnCnt** configuration symbol and **Configure** dialog tabs

Figure 8. Clock with UpCnt and DwnCnt Mode Configuration

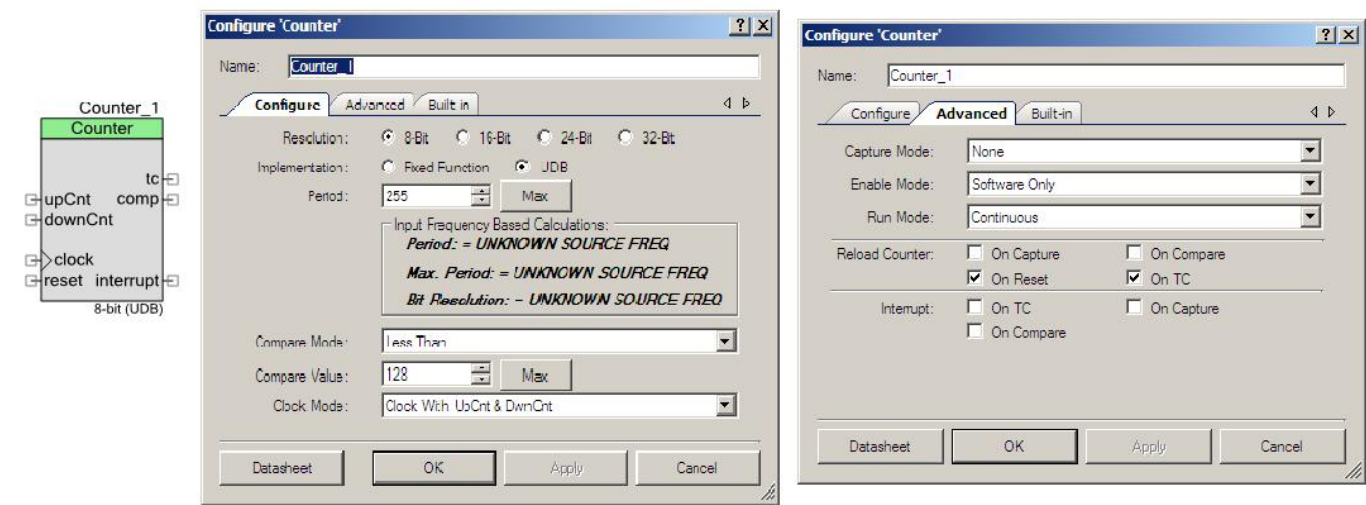

Figure 9 shows the timing diagram for the **Clock with UpCnt & DwnCnt** mode configuration

Figure 9. Clock with UpCnt and DwnCnt Mode Configuration Waveform

Event Counter Configuration

There are limitations on what signal may be applied to the count input when the **Implementation** parameter is set to **Fixed Function**. Therefore, setting the component to **UDB** can make it easier to create an event counter. In this configuration, intermittent asynchronous events can be detected and processed to generate a pulse. The clock input is used to sample this count input to produce a rising edge that causes the counter to increment or decrement, depending on the **Clock Mode** setting. The counter register can be captured and read by the CPU to determine the number of events that have occurred.

Clock Divider Configuration

Changing the **Implementation** parameter setting to **UDB** also enables a comp output. This output can be used to create a clock divider with a programmable frequency and duty cycle. With the default configuration, the comp output is a ~50-percent duty cycle clock whose frequency is 1/256 the frequency of the input clock.

Figure 10. Clock Divider Configuration

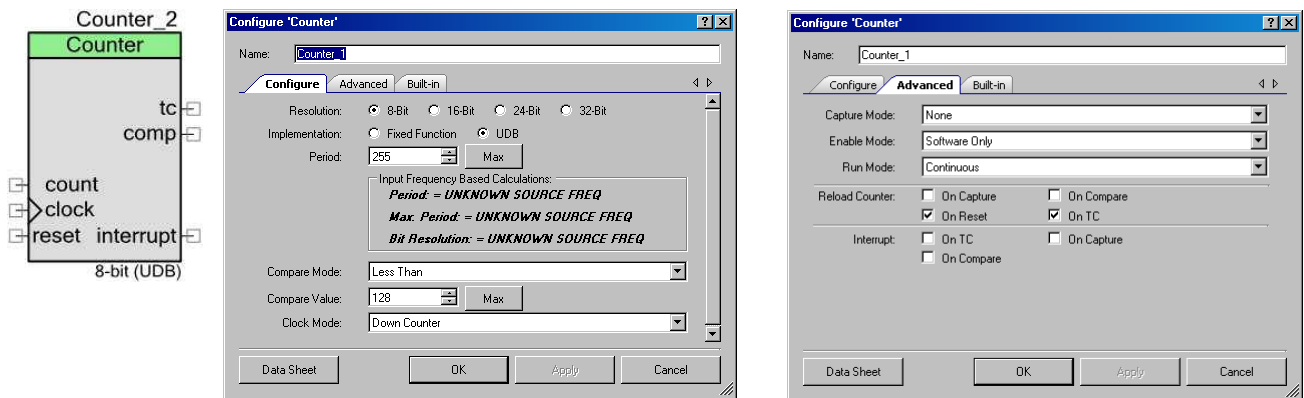

Figure 11 is an example waveform where the period is 6, the compare value is 2 and the **Compare Mode** parameter is set to **Less Than**.

Figure 11. Clock Divider Configuration Example Waveform

Frequency Counter Configuration

Adding hardware enable allows the Counter to implement a frequency counter function. If the enable input is driven by a known period signal, the frequency of a signal on the count input can be determined. The math can be simplified if the **Clock Mode** parameter is set to **Up Counter** instead of **Down Counter**.

Figure 12. Frequency Counter Configuration

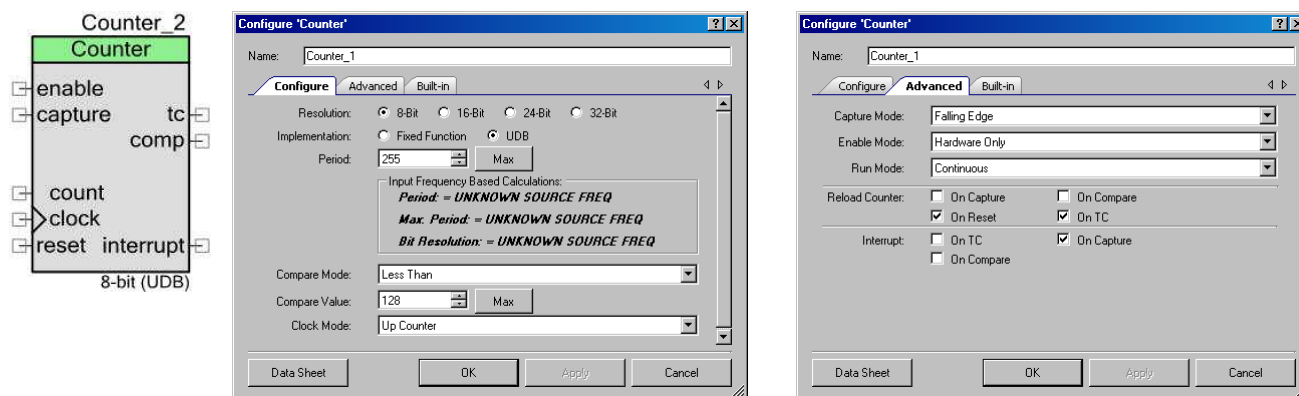

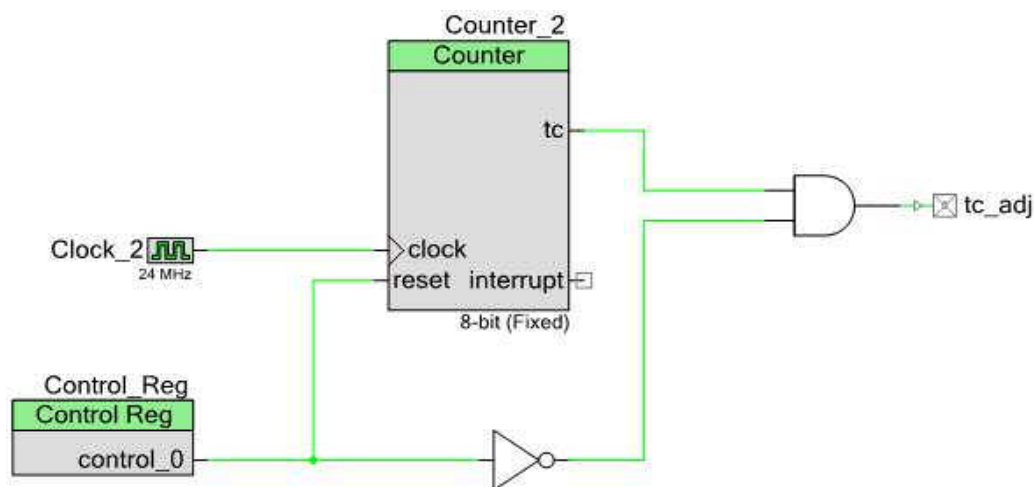

Figure 13. Frequency Counter Configuration Example Waveform

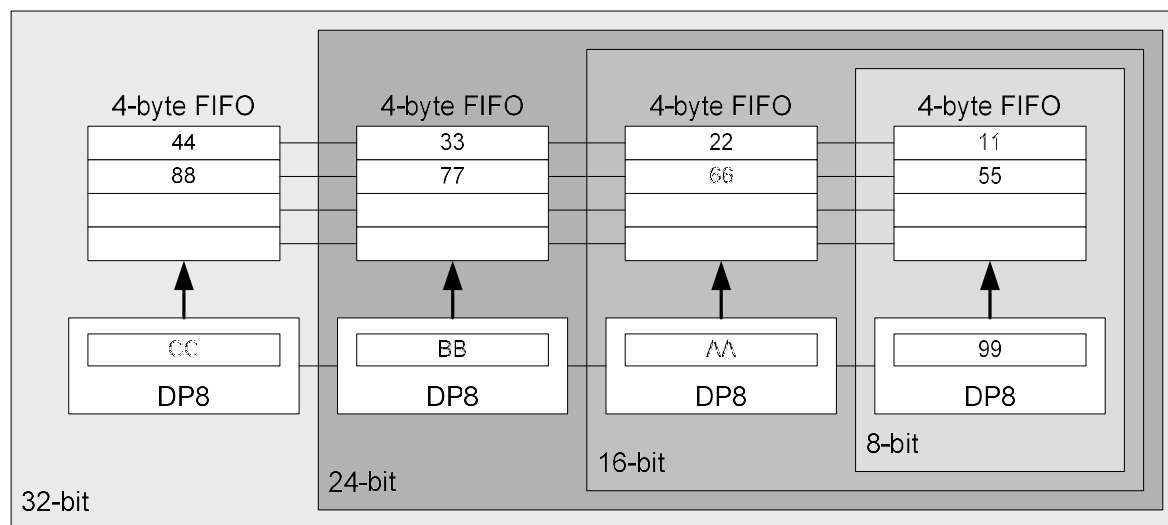

Reset in Fixed-Function Block

For PSoC 3 ES2 silicon, the FF implementation of the Counter differs from the UDB implementation in that the tc output goes high during reset. In the UDB implementation, tc goes low. Figure 14 shows a FF implementation that drives tc low while reset is active, which gives the same functionality as the UDB implementation of the same component.

Figure 14. Terminal Count Adjust Circuit for PSoC 3 ES2 Silicon

UDB FIFOs

Each UDB datapath contains two 8-bit FIFO registers: F0 and F1 (see the applicable device datasheet or TRM for details). Each FIFO is four bytes deep. The Counter UDB implementation uses one of the FIFOs as a capture register. Additional FIFOs in other datapaths are used for 16-, 24- and 32-bit counters. Therefore, up to four captures can be done before the CPU must read the capture register to avoid losing data.

Capture Value #1 = 0x44332211

Capture Value #2 = 0x88776655

Accumulator = 0xCCBBAA99

Registers

There are several constants defined to address all registers. Each of the register definitions requires either a pointer into the register data or a register address. Because different compilers have different endian settings, use the `CY_GET_REGX` and `CY_SET_REGX` macros for register accesses greater than 8 bits, with the `_PTR` definition for each of the registers. The `_PTR` definitions are provided in the generated header file.

Status Register

The status register is a read-only register that contains the status bits defined for the counter. Use the `Counter_ReadStatusRegister()` function to read the status register value. All operations on the status register must use the following defines for the bit fields as these bit fields may be different between FF and UDB implementations.

Some bits in the status register are sticky, meaning that after they are set to 1, they retain that state until cleared when the register is read. The status data is registered at the input clock edge of the counter, giving all sticky bits the timing resolution of the counter. For UDB implementation, the status register is clocked from the bus clock. For FF implementation, the status register is clocked from the timer input clock. All nonsticky bits are transparent and read directly from the inputs to the status register.

Counter_Status (UDB Implementation)

Bits	7	6	5	4	3	2	1	0
Name	RSVD	FIFO Not Empty	FIFO Full	Capture	Underflow	Overflow	Zero	Cmp
Sticky	N/A	FALSE	FALSE	TRUE	TRUE	TRUE	TRUE	TRUE

Counter_Status (Fixed Function Implementation)

Bits	7	6	5	4	3	2	1	0
Name	TC	Capture	Enable	Stop	RSVD	RSVD	RSVD	RSVD
Sticky	TRUE	TRUE	TRUE	TRUE	N/A	N/A	N/A	N/A

Bit Name	#define in header file	Description
Cmp	<code>COUNTER_STATUS_CMP</code>	This bit goes to 1 when the compare output is high.
Zero	<code>COUNTER_STATUS_ZERO</code>	This bit goes to 1 when the counter value is equal to zero.
Overflow	<code>COUNTER_STATUS_OVERFLOW</code>	This bit goes to 1 when the counter value is equal to the period value.
Underflow	<code>COUNTER_STATUS_UNDERFLOW</code>	This bit goes high when the counter value is equal to zero.

Bit Name	#define in header file	Description
Capture	Counter_STATUS_CAPTURE	This bit goes to 1 whenever a valid capture event has been triggered. This does not include software capture.
FIFO Full	Counter_STATUS_FIFOFULL	This bit goes to 1 when the UDB FIFO reaches the full state defined as four entries.
FIFO Not Empty	Counter_STATUS_FIFONEMP	This bit goes to 1 when the UDB FIFO contains at least one entry.

Mode Register

The mode register is a read/write register that contains the interrupt mask bits defined for the counter. Use the Counter_SetInterruptMode() function to set the mode bits. All operations on the mode register must use the following defines for the bit fields, as these bit fields may be different between FF and UDB implementations.

The Counter component interrupt output is an OR function of all interrupt sources. Each source can be enabled or masked by the corresponding bit in the mode register.

Counter_Mode (UDB Implementation)

Bits	7	6	5	4	3	2	1	0
Name	RSVD	FIFO Not Empty	FIFO Full	Capture	Underflow	Overflow	Zero	Cmp

Counter_Mode (Fixed Function Implementation)

Bits	7	6	5	4	3	2	1	0
Name	RSVD	RSVD	RSVD	RSVD	TC	Capture	Enable	Stop

Bit Name	#define in header file	Enables Interrupt Output On
Cmp	Counter_STATUS_CMP_INT_MASK	Compare
Zero	Counter_STATUS_ZERO_INT_MASK	Counter register equals 0
Overflow	Counter_STATUS_OVERFLOW_INT_MASK	Counter register overflow
Underflow	Counter_STATUS_UNDERFLOW_INT_MASK	Counter register underflow
Capture	Counter_STATUS_CAPTURE_INT_MASK	Capture
FIFO Full	Counter_STATUS_FIFOFULL_INT_MASK	UDB FIFO full
FIFO Not Empty	Counter_STATUS_FIFONEMP_INT_MASK	UDB FIFO not empty

Control Register

The control register allows you to control the general operation of the counter. This register is written with the `Counter_WriteControlRegister()` function and read with the `Counter_ReadControlRegister()` function. All operations on the control register must use the following defines for the bit fields as these bit-fields may be different between FF and UDB implementations.

Note When writing to the control register, you must not change any of the reserved bits. All operations must be read-modify-write with the reserved bits masked.

Counter_Control (UDB Implementation)

Bits	7	6	5	4	3	2	1	0
Name	Enable	RSVD	RSVD	Capture Mode[1:0]		Compare Mode[2:0]		

Counter_Control (Fixed Function Implementation)

Bits	7	6	5	4	3	2	1	0
Name	Enable	RSVD	RSVD	RSVD	RSVD	RSVD	RSVD	RSVD

Bit Name	#define in header file	Description / Enumerated Type
Compare Mode	Counter_CTRL_CMPMODE_MASK	<p>The compare mode control bits define the expected compare output operation. This bit field is configured at initialization with the compare mode defined in the Compare Mode parameter.</p> <ul style="list-style-type: none"> Counter__B_COUNTER__CM_LESSTHAN Counter__B_COUNTER__CM_LESSTHANOEQUAL Counter__B_COUNTER__CM_EQUAL Counter__B_COUNTER__CM_GREATERTHAN Counter__B_COUNTER__CM_GREATERTHANOEQUAL
Capture Mode	Counter_CTRL_CAPMODE_MASK	<p>The capture mode control bits are a two-bit field that defines the expected capture input operation. This bit field is configured at initialization with the capture mode defined in the Capture Mode parameter.</p> <ul style="list-style-type: none"> Counter__B_COUNTER__CPTM_NONE Counter__B_COUNTER__CPTM_RISINGEDGE Counter__B_COUNTER__CPTM_FALLINGEDGE Counter__B_COUNTER__CPTM_EITHEREDGE
Enable	Counter_CTRL_ENABLE	<p>This bit enables counting under software control. This bit is valid only if the Enable Mode parameter is set to Software Only or Hardware and Software.</p>

Counter (8-, 16-, 24-, or 32-bit based on Resolution)

The counter register contains the current counter value. This register is incremented or decremented in response to various count/clock inputs. This register may be read at any time with the `Counter_ReadCounter()` function.

Capture (8-, 16-, 24-, or 32-bit based on Resolution)

The capture register contains the captured counter value. Any capture event copies the counter register to this register. In UDB implementation, this register is actually a FIFO. See the [UDB FIFOs](#) section for details.

Period (8-, 16-, 24-, or 32-bit based on Resolution)

The period register contains the period value set through the `Counter_WritePeriod()` function and defined by the **Period** parameter at initialization. The period register is copied into the counter register on a reload event.

Compare (8-, 16-, 24-, or 32-bit based on Resolution)

The compare register contains the compare value used to determine the state of the compare (comp) output.

DC and AC Electrical Characteristics (FF Implementation)

The following values indicate expected performance and are based on initial characterization data.

Counter DC Specifications

Parameter	Description	Conditions	Min	Typ	Max	Units
	Block current consumption	16-bit counter, at listed input clock frequency	–	–	–	μA
	3 MHz		–	15	–	μA
	12 MHz		–	60	–	μA
	48 MHz		–	260	–	μA
	67 MHz		–	350	–	μA

Counter AC Specifications

Parameter	Description	Conditions	Min	Typ	Max	Units
	Operating frequency	PSoC 3	DC	–	67	MHz
	Capture pulse		15	–	–	ns
	Resolution		15	–	–	ns
	Pulse width		15	–	–	ns
	Pulse width (external)		30	–	–	ns
	Enable pulse width		15	–	–	ns
	Enable pulse width (external)		30	–	–	ns
	Reset pulse width		15	–	–	ns
	Reset pulse width (external)		30	–	–	ns

DC and AC Electrical Characteristics (UDB Implementation)

The following values indicate expected performance and are based on initial characterization data.

Timing Characteristics “Maximum with Nominal Routing”

Parameter	Description	Config. ¹	Min	Typ	Max	Units
f _{CLOCK}	Component clock frequency	Config 1	–	–	45	MHz
		Config 2	–	–	40	MHz
		Config 3	–	–	35	MHz
		Config 4	–	–	30	MHz
		Config 5	–	–	25	MHz

¹Configurations:

Config 1:

t_{IL}	Input low time	1,2,3,4	t_{CY_clock}	—	—	ns

How to Use STA Results for Characteristics Data

Nominal route maximums are gathered through multiple test passes with Static Timing Analysis (STA). You can calculate the maximums for your designs from the STA results using the following methods:

f_{CLOCK} Maximum Component Clock Frequency appears in Timing results in the clock summary as the named external clock. The graphic below shows an example of the clock limitations from the *_timing.html*:

–Clock Summary

Clock	Actual Freq	Max Freq	Violation
BUS_CLK	24.000 MHz	118.683 MHz	
clock	24.000 MHz	56.967 MHz	

Input Path Delay and Pulse Width

When characterizing the functionality of inputs, all inputs, no matter how you have configured them, look like one of four possible configurations, as shown in [Figure 15](#).

All inputs must be synchronized. The synchronization mechanism depends on the source of the input to the component. To interpret how your system will work, you must understand which input configuration you have set up for each input and the clock configuration of your system. This section describes how to use the Static Timing Analysis (STA) results to determine the characteristics of your system.

Figure 15. Input Configurations for Component Timing Specifications

Configuration	Component Clock	Synchronizer Clock (Frequency)	Figures
1	master_clock	master_clock	Figure 20
1	clock	master_clock	Figure 18

1	clock	clockX < clock	Figure 19
2	master_clock	master_clock	Figure 20
2	clock	master_clock	Figure 18
3	master_clock	master_clock	Figure 25

¹ Clock frequencies are equal but alignment of rising edges is not guaranteed.

Configuration	Component Clock	Synchronizer Clock (Frequency)	Figures
3	clock	master_clock	Figure 23
3	clock	clockX = clock ¹	Figure 21
3	clock	clockX > clock	Figure 22
3	clock	clockX < clock	Figure 24
4	master_clock	master_clock	Figure 25
4	clock	clock	Figure 21

1. The input is driven by a device pin and synchronized internally with a “sync” component. This component is clocked using a different internal clock than the clock the component uses (all internal clocks are derived from master_clock).

When characterizing inputs configured in this way clockX may be faster than, equal to, or slower than the component clock. It may also be equal to master_clock. This produces the characterization parameters shown in [Figure 16](#), [Figure 17](#), [Figure 19](#), and [Figure 20](#).

2. The input is driven by a device pin and synchronized at the pin using master_clock.

When characterizing inputs configured in this way, master_clock is faster than or equal to the component clock (it is never slower than). This produces the characterization parameters shown in [Figure 17](#) and [Figure 20](#).

Figure 16. Input Configuration 1 and 2; Sync Clock Frequency = Component Clock Frequency (Edge alignment of clock and clockX is not guaranteed)

Figure 17. Input Configuration 1 and 2; Sync. Clock Frequency > Component Clock Frequency

Figure 18. Input Configuration 1 and 2; [Sync. Clock Frequency == master_clock] > Component Clock Frequency

Figure 19. Input Configuration 1; Sync. Clock Frequency < Component Clock Frequency**Figure 20. Input Configuration 1 and 2; Sync. Clock = Component Clock = master_clock**

- The input is driven by logic internal to the PSoC. This logic is synchronous based on a clock other than the clock the component uses (all internal clocks are derived from master_clock).
When characterizing inputs configured in this way, the synchronizer clock is faster than, slower than, or equal to the component clock. This produces the characterization parameters shown in [Figure 21](#), [Figure 22](#), and [Figure 24](#).
- The input is driven by logic internal to the PSoC. This logic is synchronous based on the same clock the component uses.

When characterizing inputs configured in this way, the synchronizer clock is equal to the component clock. This produces the characterization parameters shown in [Figure 25](#).

Figure 21. Input Configuration 3 only; Sync. Clock Frequency = Component Clock Frequency (Edge alignment of clock and clockX is not guaranteed)

[Figure 21](#) the information that Static Timing Analysis has on the clocks. All clocks in the digital clock domain are synchronous to master_clock. However, two clocks with the same frequency may not be rising-edge-aligned. Therefore, the Static Timing Analysis tool does not know which edge the clocks are synchronous to and must assume the minimum of one master_clock cycle. This means that t_{PD_si} now has a limiting effect on the system's master_clock. master_clock setup time violations appear if this path delay is too long. You must change the synchronization clocks of your system or run master_clock at a slower frequency.

Figure 22. Input Configuration 3; Sync. Clock Freq. > Component Clock Freq.

In much the same way as shown in [Figure 21](#), all clocks are derived from master_clock. STA indicates the t_{PD_si} limitations on master_clock for one master_clock cycle in this configuration. master_clock setup time violations appear if this path delay is too long. You must change the synchronization clocks of your system or run the master_clock at a slower frequency.

Figure 23. Input Configuration 3; Synchronizer Clock Frequency = master_clock > Component Clock Frequency

Figure 24. Input Configuration 3; Synchronizer Clock Frequency < Component Clock Frequency

In much the same way as shown in [Figure 21](#), all clocks are derived from master_clock. STA indicates the t_{PD_si} limitations on master_clock for one master_clock cycle in this configuration. master_clock setup time violations appear if this path delay is too long. You must change the synchronization clocks of your system or run master_clock at a slower frequency.

Figure 25. Input Configuration 4 only; Synchronizer Clock = Component Clock

In all previous figures in this section, the most critical parameters to use when understanding your implementation are f_{CLOCK} and $t_{\text{PD_IE}}$. $t_{\text{PD_IE}}$ is defined by $t_{\text{PD_ps}}$ and t_{SYNC} (for configurations 1 and 2 only), $t_{\text{PD_si}}$, and $t_{\text{I_Clk}}$. It is very important to note that $t_{\text{PD_si}}$ defines the maximum component clock frequency. $t_{\text{I_Clk}}$ does not come from the STA results but is used to represent when $t_{\text{PD_IE}}$ is registered. This is the margin left over after the route between the synchronizer and the component clock.

$t_{\text{PD_ps}}$ and $t_{\text{PD_si}}$ are included in the STA results.

To find $t_{\text{PD_ps}}$, look at the input setup times defined in the *_timing.html* file. The fanout of this input may be more than 1 so you will need to evaluate the maximum of these paths.

-Setup times

-Setup times to clock BUS_CLK

Start	Register	Clock	Delay (ns)
input1(0):iocell.pad_in	input1(0):iocell.ind	BUS_CLK	16.500

$t_{\text{PD_si}}$ is defined in the Register-to-register times. You need to know the name of the net to use the *_timing.html* file. The fanout of this path may be more than 1 so you will need to evaluate the maximum of these paths.

-Register-to-register times

-Destination clock clock

Destination clock clock (Actual freq: 24.000 MHz)

+Source clock clock

-Source clock clock_1

Source clock clock_1 (Actual freq: 24.000 MHz)

Affected clock: BUS_CLK (Actual freq: 24.000 MHz)

Start	End	Period (ns)	Max Freq	Frequency	Violation
\Sync_1:genblk1[0]:INST\:\synccell.syncq	\PWM_1:PWMUDB:runmode_enable\:\macrocell.mc_d	7.843	127.508 MHz	24.000 MHz	

Output Path Delays

When characterizing the path delays of outputs, you must consider where the output is going in order to know where you can find the data in the STA results. For this component, all outputs are synchronized to the component clock. Outputs fall into one of two categories. The output goes either to another component inside the device, or to a pin to the outside of the device. In the first case, you must look at the Register-to-register times shown for the Logic-to-input descriptions (the source clock is the component clock). For the second case, you can look at the Clock-to-Output times in the *_timing.html* STA results.

Component Changes

This section lists the major changes in the component from the previous version.

Version	Description of Changes	Reason for Changes / Impact
2.0.a	Updated Resource information in datasheet	
	Added additional configuration sections to datasheet	
2.0	Redesigned as a synchronous counter with over-sampling in all modes.	The architecture of the device and the tool has proven that a synchronous design is the only viable solution. All modes are still supported but require a clock for oversampling.
	Removed “comp” terminal from fixed-function implementation	The implementation does not support a compare output. The pin is now correctly hidden.
	Synchronized inputs	All inputs are synchronized in fixed-function implementation, at the input of the block.
	Counter_GetInterruptSource() function was converted to a macro	The Counter_GetInterruptSource() function is exactly the same implementation as the Counter_ReadStatusRegister() function. To save code space this was converted to a macro substitution of the Counter_ReadStatusRegister() function.
	Outputs are now registered to the component clock	To avoid glitches on the outputs of the component it was required that all outputs be synchronized. This is done inside of the datapath when possible, to avoid using too many resources.
	Implemented critical regions when writing to Aux Control registers.	CyEnterCriticalSection and CyExitCriticalSection functions are used when writing to Aux Control registers so that it is not modified by any other process thread.
	Added characterization data to datasheet	
	Minor datasheet edits and updates
